CMOS Programmable Bit Rate Generator

Features

- This Circuit is Processed in Accordance to MIL-STD-883 and is Fully Conformant Under the Provisions of Paragraph 1. 2. 1.
- HD-4702/883 Provides 13 Commonly Used Bit Rates
- Uses a 2.4576MHz Crystal/Input for Standard Frequency Output (16 Times Bit Rate)
- Low Power Dissipation
- Conforms to EIA RS-404
- One HD-4702/883 Controls up to Eight Transmission Channels
- Initialization Circuit Facilitates Diagnostic Fault Isolation
- On-Chip Input Pull-Up Circuit

Description

The HD-4702/883 Bit Rate Generator provides the necessary clock signals for digital data transmission systems, such as a UART. It generates 13 commonly used bit rates using an on-chip crystal oscillator or an external input. For conventional operation generating 16 output clock pulses per bit period, the input clock frequency must be 2.4576MHz (i.e., 9600 Baud x 16 x 16, since there is an internal ÷ 16 prescaler). A lower input frequency will result in a proportionally lower output frequency.

The HD-4702/883 can provide multi-channel operation with a minimum of external logic by having the clock frequency C_O and the ÷ 8 prescaler outputs Q_0 , Q_1 , Q_2 available externally. All signals have a 50% duty cycle except 1800 Baud, which has less than 0.39% distortion.

The four rate select inputs (S_0 - S_3) select which bit rate is at the output (Z). See Truth Table for Rate Select Inputs for select code and output bit rate. Two of the 16 select codes for the HD-4702/883 do not select an internally generated frequency, but select an input into which the user can feed either a different frequency, or a static level (High or Low) to generate "ZERO BAUD".

The bit rates most commonly used in modern data terminals (110,150, 300,1200, 2400 Baud) require that no more than one input be grounded for the HD-4702/883, which is easily achieved with a single 5-position switch.

The HD-4702/883 has an initialization circuit which generates a master reset for the scan counter. This signal is derived from a digital differentiator that senses the first high level on the C_P input after the $\overline{E}_{CP}$ input goes low. When $\overline{E}_{CP}$ is high, selecting the crystal input, C_P must be low. A high level on C_P would apply a continuous reset. See Clock Modes and Initialization below.

NOTES:

- Propagation Delays (t_{PLH} and t_{PHL}) and Output Transition Times (t_{TLH} and t_{THL}) will change with Output Load Capacitance (C_L). Set-Up Times (t_S), Hold Times (t_H), and Minimum Pulse Widths (t_W) do not vary with load capacitance.
- For multichannel operation, Propagation Delay (C_O to Q_n), plus Set-Up Time, Select to C_O , is guaranteed to be $\leq 367ns$.
- The first High Level Clock Pulse after $\overline{ECP}$ goes Low must be at least 350ns long to guarantee reset of all Counters.
- It is recommended that input rise and fall times to the clock inputs (C_P , I_X) be less than 15ns.

1. Index area: A notch or a pin one identification mark shall be located adjacent to pin one and shall be located within the shaded area shown. The manufacturer's identification shall not be used as a pin one identification mark.
2. The maximum limits of lead dimensions b and c or M shall be measured at the centroid of the finished lead surfaces, when solder dip or tin plate lead finish is applied.
3. Dimensions b1 and c1 apply to lead base metal only. Dimension M applies to lead plating and finish thickness.
4. Corner leads (1, N, N/2, and N/2+1) may be configured with a partial lead paddle. For this configuration dimension b3 replaces dimension b2.
5. This dimension allows for off-center lid, meniscus, and glass overrun.
6. Dimension Q shall be measured from the seating plane to the base plane.
7. Measure dimension S1 at all four corners.
8. N is the maximum number of terminal positions.
9. Dimensioning and tolerancing per ANSI Y14.5M - 1982.
10. Controlling dimension: INCH.
