

# MAXIM

## Low-Power, 16-Bit Smart ADC

MAX1460

### General Description

The MAX1460 implements a revolutionary concept in signal conditioning, where the output of its 16-bit analog-to-digital converter (ADC) is digitally corrected over the specified temperature range. This feature can be readily exploited by automotive, industrial, and medical market segments, in applications such as sensors and smart batteries. Digital correction is provided by an internal digital signal processor (DSP) and on-chip 128-bit EEPROM containing user-programmed calibration coefficients. The conditioned output is available as a 12-bit digital word and as a ratiometric (proportional to the supply voltage) analog voltage using an on-board 12-bit digital-to-analog converter (DAC). The uncommitted op amp can be used to filter the analog output, or implement a 2-wire, 4–20mA transmitter.

The analog front end includes a 2-bit programmable-gain amplifier (PGA) and a 3-bit coarse-offset (CO) DAC, which condition the sensor's output. This coarsely corrected signal is digitized by a 16-bit ADC. The DSP uses the digitized sensor signal, the temperature sensor, and correction coefficients stored in the internal EEPROM to produce the conditioned output.

Multiple or batch manufacturing of sensors is supported with a completely digital test interface. Built-in testability features on the MAX1460 result in the integration of three traditional sensor-manufacturing operations into one automated process:

- **Pretest:** Data acquisition of sensor performance under the control of a host test computer.
- **Calibration and Compensation:** Computation and storage of calibration and compensation coefficients determined from transducer pretest data.
- **Final Test Operation:** Verification of transducer calibration and compensation, without removal from the pretest socket.

The MAX1460 evaluation kit (EV kit) allows fast evaluation and prototyping, using a piezoresistive transducer (PRT) and a Windows®-based PC. The user-friendly EV kit simplifies small-volume prototyping; it is not necessary to fully understand the test-system interface, the calibration algorithm, or many other details to evaluate the MAX1460 with a particular sensor. Simply plug the PRT into the EV kit, plug the EV kit into a PC parallel port, connect the sensor to an excitation source (such as a pressure controller), and run the MAX1460 EV kit software. An oven is required for thermal compensation.

### Features

- ◆ **Low-Noise, 400µA Single-Chip Sensor Signal Conditioning**
- ◆ **High-Precision Front End Resolves Less than 1µV of Differential Input Signal**
- ◆ **On-Chip DSP and EEPROM Provide Digital Correction of Sensor Errors**
- ◆ **16-Bit Signal Path Compensates Sensor Offset and Sensitivity and Associated Temperature Coefficients**
- ◆ **12-Bit Parallel Digital Output**
- ◆ **Analog Output**
- ◆ **Compensates a Wide Range of Sensor Sensitivity and Offset**
- ◆ **Single-Shot Automated Compensation Algorithm—No Iteration Required**
- ◆ **Built-In Temperature Sensor**
- ◆ **Three-State, 5-Wire Serial Interface Supports High-Volume Manufacturing**

### Applications

Hand-Held Instruments  
Piezoresistive Pressure and Acceleration Transducers and Transmitters  
Industrial Pressure Sensors and 4–20mA Transmitters  
Smart Battery Charge Systems  
Weigh Scales and Strain-Gauge Measurement  
Flow Meters  
Dive Computers and Liquid-Level Sensing  
Hydraulic Systems  
Automotive Systems

### Ordering Information

PART	TEMP. RANGE	PIN-PACKAGE
MAX1460CCM	0°C to +70°C	48 TQFP

### Customization

Maxim can customize the MAX1460 for unique requirements. With a dedicated cell library of more than 90 sensor-specific functional blocks, Maxim can quickly provide customized MAX1460 solutions, including customized microcode for unusual sensor characteristics. Contact Maxim for further information.

# Low-Power, 16-Bit Smart ADC

## ABSOLUTE MAXIMUM RATINGS

Supply Voltage, $V_{DD}$ to $V_{SS}$ .....	-0.3V to +6V	Operating Temperature Range.....	0°C to +70°C
All Other Pins .....	( $V_{SS} - 0.3V$ ) to ( $V_{DD} + 0.3V$ )	Storage Temperature Range .....	-65°C to +160°C
Short-Circuit Duration, All Outputs .....	Continuous	Lead Temperature (soldering, 10sec) .....	+300°C
Continuous Power Dissipation ( $T_A = +70^\circ\text{C}$ )			
48-Pin TQFP (derate 12.5mW/°C above +70°C ).....	1000mW		

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ELECTRICAL CHARACTERISTICS

Three-State Leakage Current	$I_L$	CS = 0			$\pm 10$	$\mu A$
Three-State Output Capacitance	$C_{OUT}$	CS = 0 (Note 10)			50.0	pF
<b>DIGITAL OUTPUTS: SDIO (Note 8), SDO, EOC, OUT</b>						
Output Voltage Low	$V_{OL}$	$I_{SINK} = 500\mu A$		0.3		V
Output Voltage High	$V_{OH}$	$I_{SOURCE} = 500\mu A$		4.7		V
Three-State Leakage Current	$I_L$	CS = 0		$\pm 10$		$\mu A$
Three-State Output Capacitance	$C_{OUT}$	CS = 0 (Note 10)			50.0	pF

**Note 1:** EEPROM programming requires a minimum  $V_{DD} = 4.75V$ .  $I_{DD}$  may exceed its limits during this time.

**Note 2:** This value does not include the sensor or load current. This value does include the uncommitted op amp current. Note that the MAX1460 will convert continuously if REPEAT MODE is set in the EEPROM.

**Note 3:** See the *Analog Front-End, including PGA, Coarse Offset DAC, ADC, and Temperature Sensor* sections.

**Note 4:** The signal input to the ADC is the output of the PGA plus the output of the CO-DAC. The reference to the ADC is  $V_{DD}$ . The plus full-scale input to the ADC is  $+V_{DD}$  and the minus full-scale input to the ADC is  $-V_{DD}$ . This specification shows the contribution of the CO-DAC to the ADC input.

**Note 5:** See Figure 2 for ADC outputs between  $+0.8500$  to  $-0.8500$ .

**Note 6:** The sensor and the MAX1460 must always be at the same temperature during calibration and use.

**Note 7:** The Output DAC is specified using the external lowpass filter (Figure 8).

**Note 8:** SDIO is an input/output digital pin. It is only enabled as a digital output pin when the MAX1460 receives from the test system the commands 8 hex or A hex (Table 4).

**Note 9:** XIN is a digital input pin only when the TEST pin is high.

**Note 10:** Guaranteed by design. Not subject to production testing.

# Low-Power, 16-Bit Smart ADC

## Pin Description

PIN	NAME	FUNCTION
1, 2, 12, 13, 18, 19, 31, 32, 36, 41–45	N.C.	No Connection. Not internally connected.
3	AGND	Analog Ground. Connect to $V_{DD}$ and $V_{SS}$ using 10k $\Omega$ resistors (see <i>Functional Diagram</i> ).
4	START	Optional conversion start input signal, used for extending sensor warm-up time. Internally pulled to $V_{DD}$ with a 1M $\Omega$ (typical) resistor.
5	I.C.	Internally Connected. Leave unconnected.
6	D6	Parallel Digital Output - bit 6
7	D7	Parallel Digital Output - bit 7
8	D8	Parallel Digital Output - bit 8
9	D9	Parallel Digital Output - bit 9
10	D10	Parallel Digital Output - bit 10
11	D11	Parallel Digital Output - bit 11 (MSB)
14, 37, 38	$V_{DD}$	Positive Supply Voltage Input. Connect a 0.1 $\mu$ F bypass capacitor from $V_{DD}$ to $V_{SS}$ . Pins 14, 37, and 38 must all be connected to the positive power supply on the PCB.
15	$V_{SS}$	Negative Supply Input
16, 17	CS1, CS2	Chip-Select Input. The MAX1460 is selected when CS1 and CS2 are both high. When either CS1 or CS2 is low, all digital outputs are high impedance and all digital inputs are ignored. CS1 and CS2 are internally pulled high to $V_{DD}$ with a 1M $\Omega$ (typical) resistor.
20	SDIO	Serial Data Input/Output. Used only during programming/testing, when the TEST pin is high. The test system sends commands to the MAX1460 through SDIO. The MAX1460 returns the current instruction ROM address and data being executed by the DSP to the test system. SDIO is internally pulled to $V_{SS}$ with a 1M $\Omega$ (typical) resistor. SDIO goes high impedance when either CS1 or CS2 is low and remains in this state until the test system initiates conversion.
21	SDO	Serial Data Output. Used only during programming/testing. SDO allows the test system to monitor the DSP registers. The MAX1460 returns to the test system results of the DSP current instruction. SDO is high impedance when TEST is low.
22	$\overline{\text{RESET}}$	Reset Input. When TEST is high, a low-to-high transition on $\overline{\text{RESET}}$ enables the MAX1460 to accept commands from the test system. This input is ignored when TEST is low. Internally pulled high to $V_{DD}$ with a 1M $\Omega$ (typical) resistor.
23	EOC	End of Conversion Output. A high-to-low transition of the EOC pulse can be used to latch the Parallel Digital Output (pins D[11...0]).
24	D0	Parallel Digital Output - bit 0 (LSB)
25	D1	Parallel Digital Output - bit 1
26	D2	Parallel Digital Output - bit 2

# Low-Power, 16-Bit Smart ADC

**MAX1460**

## Pin Description (continued)

PIN	NAME	FUNCTION
27	D3	Parallel Digital Output - bit 3
28	D4	Parallel Digital Output - bit 4
29	D5	Parallel Digital Output - bit 5
30	OUT	Output DAC. The bitstream on OUT, when externally filtered, creates a ratiometric analog output voltage. OUT is proportional to the 12-bit parallel digital output.
33	AMPOUT	General-Purpose Operational Amplifier Output
34	AMP+	Noninverting Input of General-Purpose Operational Amplifier
35	AMP-	Inverting Input of General-Purpose Operational Amplifier
39	XOUT	Internal Oscillator Output. Connect a 2MHz ceramic resonator (Murata CST200) or crystal from XOUT to XIN.
40	XIN	Internal Oscillator Input. When TEST is high, this pin must be driven by the test system with a 2MHz, 50% duty cycle clock signal. The resonator does not need to be disconnected in test mode.
46	INP	Positive Sensor Input. Input impedance is typically > 1M $\Omega$ . Rail-to-Rail <sup>®</sup> input range.
47	TEST	Test/Program Mode Enable Input. When high, enables the MAX1460 programming/testing operations. Internally pulled to V <sub>SS</sub> with a 1M $\Omega$ (typical) resistor.
48	INM	Negative Sensor Input. Input impedance is typically > 1M $\Omega$ . Rail-to-rail input range.

*Rail-to-Rail is a registered trademark of Nippon Motorola, Ltd.*

# Low-Power, 16-Bit Smart ADC

## Detailed Description

The main functions of the MAX1460 include:

- Analog Front End: Includes PGA, coarse-offset DAC, ADC, and temperature sensor
- Test System Interface: Writes calibration coefficients to the DSP registers and EEPROM
- Test System Interface: observes the DSP operation.

The sensor signal enters the MAX1460 and is adjusted for coarse gain and offset by the analog front end. Five bits in the configuration register set the coarse-offset DAC and the coarse gain of the PGA (Tables 1 and 2). These bits must be properly configured for the optimum dynamic range of the ADC. The digitized sensor signal is stored in a read-only DSP register.

The on-chip temperature sensor also has a 3-bit coarse-offset DAC that places the temperature signal in the ADC operating range. Digitized temperature is also stored in a read-only DSP register. The DSP uses the digitized sensor, the temperature signals, and the correction coefficients to calculate the compensated and corrected output.

The MAX1460 supports an automated production environment, where a test system communicates with a batch of MAX1460s and controls temperature and sen-

sor excitation. The three-state digital outputs on the MAX1460 allow parallel connection of transducers, so that all five serial interface lines (XIN, TEST, RESET, SDIO, and SDO) can be shared. The test system selects an individual transducer using CS1 and CS2. The test system must vary the sensor's input and temperature, calculate the correction coefficients for each unit, load the coefficients into the MAX1460 nonvolatile EEPROM, and test the resulting compensation.

The MAX1460 DSP implements the following characteristic equation:

$$D = \text{Gain} (1 + G_1T + G_2T^2) \left( \text{Signal} + \text{Of}_0 + \text{Of}_1T + \text{Of}_2T^2 \right) + \text{D}_{\text{OFF}}$$

where Gain corrects the sensor's sensitivity,  $G_1$  and  $G_2$  correct for Gain-TC,  $T$  and Signal are the digitized outputs of the analog front end,  $\text{Of}_0$  corrects the sensor's offset,  $\text{Of}_1$  and  $\text{Of}_2$  correct the Offset-TC, and  $\text{D}_{\text{OFF}}$  is the output offset pedestal.

The test system can write the calibration coefficients into the MAX1460 EEPROM or write to the DSP registers directly. The MAX1460 can begin a conversion using either the EEPROM contents or the register contents. When the test system issues commands, the MAX1460 is a serially controlled slave device.

The test system observes the MAX1460 DSP operation in order to acquire the temperature and signal ADC results, to verify the calibration coefficients, and to get the output  $D$ . The MAX1460 places the contents of several important DSP registers on the serial interface after the tester issues a Start Conversion command.

After calibration, compensation, and final test, the MAX1460 is adapted to its sensor and the pair can be removed from the test system. Use the resulting trans-

# Low-Power, 16-Bit Smart ADC

ducer by applying power and the START signal. Latch the 12-bit parallel digital output using the EOC pulse. The maximum conversion rate of the MAX1460 is 15Hz, using a 2MHz resonator. If an analog output is desired, build a simple lowpass filter using the OUT pin, the uncommitted op amp, and a few discrete components (Figure 8).

**Analog Front End, Including PGA, Coarse Offset DAC, ADC, and Temperature Sensor**  
 Before the sensor signal is digitized, it must be gained and coarse-offset corrected to maximize the ADC dynamic range. There are 2 bits (four possible settings) in the configuration register for the PGA gain, and 3 bits (eight possible settings) for the CO DAC. The flowchart (Figure 1) shows a procedure for finding the optimum

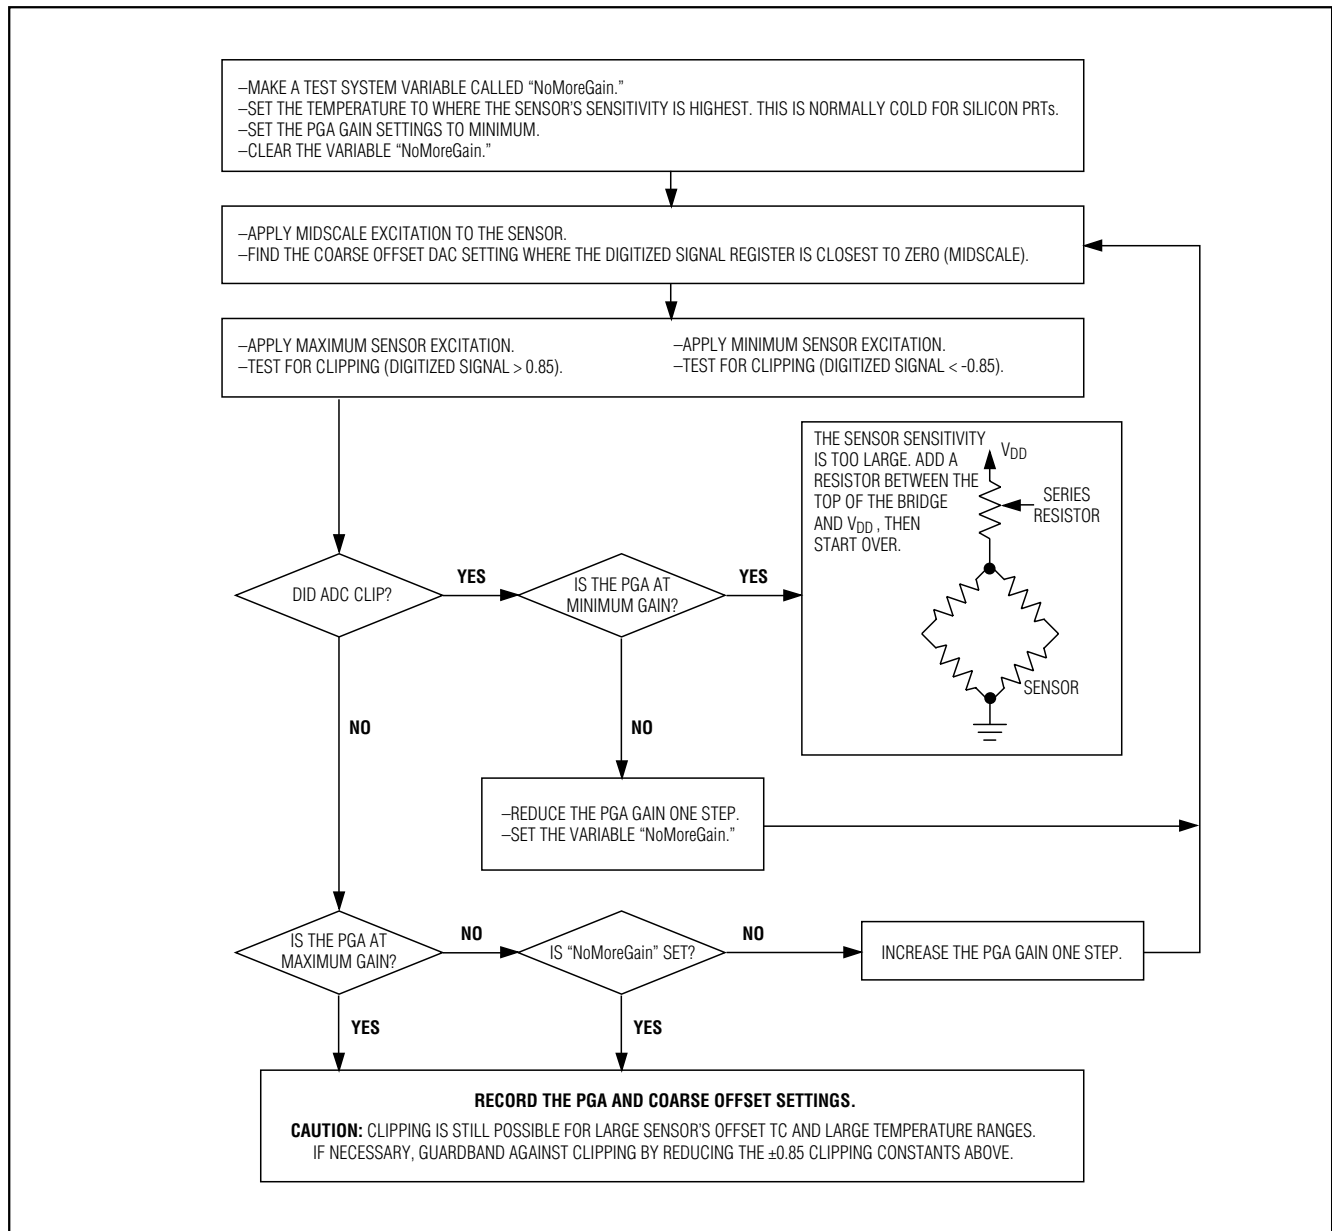

Figure 1. Flowchart for Determining PGA and CO Settings

# Low-Power, 16-Bit Smart ADC

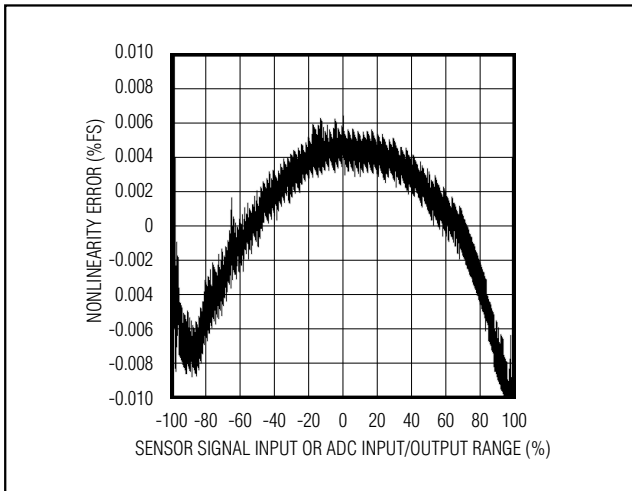

Figure 2a. Analog Front-End INL (typical)

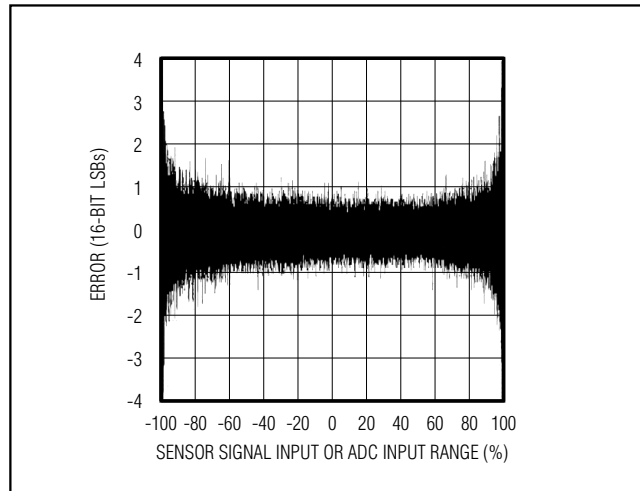

Figure 2b. Analog Front-End Differential Nonlinearity (DNL) (typical)

Figure 2c. Analog Front-End Noise Standard Deviation of the Samples (typical)

analog front-end settings when the sensor's characteristics are unknown. Use the tabulated values (Tables 1 and 2) if the peak sensor excursions are known. See the *Test System Interface* section for details on writing these analog front-end bits.

The PGA gain and the CO are very stable, but are not accurate. Manufacturing variances on the gain and offset of the MAX1460 analog front-end superposition the residual sensor errors, and are later removed during final calibration.

For example, suppose the sensor's sensitivity is +10mV/V with an offset of -12mV/V. Let the supply volt-

age be +5V. The full scale (-FS) output of the sensor is then +5V(-12mV/V) = -60mV; +FS is then +5V (-12mV/V + 10mV/V) = -10mV. Following through the flowchart, the PGA gain setting is +3 (gain = 93V/V) and the CO correction setting is +1 (+25mV RTI) - (Referred-to-Input). The coarsely corrected -FS input to the ADC is (-60mV + 25mV)93 = -3.255V. The +FS input to the ADC is (-10mV + 25mV)93 = +1.395V. The input range of the ADC is  $\pm V_{DD}$ . Thus the maximum and minimum digitized sensor signals become  $-3.255 / 5 = -0.651$  and  $+1.395 / 5 = +0.279$ .

Notice that the bridge multiplies the signal by  $V_{DD}$  and the ADC divides the signal by  $V_{DD}$ . Thus, the system is ratiometric and not dependent on the DC value of  $V_{DD}$ . The ADC output clips to  $\pm 1.0$  when input values exceed  $\pm V_{DD}$ . The best signal-to-noise ratio (SNR) is achieved when the ADC input is within  $\pm 85\%$  of  $V_{DD}$  (Figure 2).

The MAX1460 includes an internal temperature-sensing bridge allowing the MAX1460 temperature to be used as a proxy for the sensor temperature. For this reason, the MAX1460 must be mounted in thermal proximity to the sensor. The output of the temperature-sensing bridge is also corrected by a 3-bit coarse-offset DAC and processed by the ADC. The selection of the Temperature Sensor Offset (TSO) bits in the configuration register should be made so that the digitized temperature signal is as close to 0.0 as possible at midscale temperature. This is done to maximize the dynamic range of the thermal-calibration coefficients (Table 3).

### Test-System Interface: Writing Calibration Coefficients to the DSP Registers and EEPROM

To make the MAX1460 respond to commands from the test system, raise the TEST pin and drive XIN with a 2MHz clock signal. It is not necessary to remove the resonator. RESET must be low for at least 16 clock cycles to initialize the MAX1460. Then, a rising transi-

tion on RESET begins a 32-bit serial transfer of the test-system command word through SDIO. The test system transitions SDIO on falling edges of the XIN clock; the MAX1460 latches data on the rising edge (Figure 3).

The 32-bit command word generated by the test-system is divided into four fields (Figure 3). The 4-bit command field is interpreted in Table 4. The other fields are usually ignored, except that command 1 hex uses the two register fields, and command 2 hex requires an EEPROM address. The command word fields are:

- Register Data Field: Holds the calibration coefficients to be written into the MAX1460 16-bit registers
- EEPROM Address Field: Holds the hexadecimal address of the EEPROM bit to be set (from 00 hex to 7F hex)
- Register Address Field: Contains the address of the register (0 to 7) where the calibration coefficient is to be written
- Command Field: Instructs the MAX1460 to take a particular action (Table 4)

# Low-Power, 16-Bit Smart ADC

**Table 4. Test System Commands**

COMMAND	HEX CODE	C3	C2	C1	C0
Write a calibration coefficient into a DSP register.	1 hex	0	0	0	1
Block-Erase the entire EEPROM (writes "0" to all 128 bits).	4 hex	0	1	0	0
Write "1" to a single EEPROM bit.	2 hex	0	0	1	0
NOOP (NO-OPeration)	0 hex	0	0	0	0
Start Conversion command. The registers are not updated with EEPROM values. SDIO and SDO are enabled as DSP outputs.	8 hex	1	0	0	0
Start Conversion command. The registers are updated with EEPROM values. SDIO and SDO are enabled as DSP outputs.	A hex	1	0	1	0
Start Conversion command. The registers are not updated with EEPROM values. SDIO and SDO are disabled.	C hex	1	1	0	0
Start Conversion command. The registers are updated with EEPROM values. SDIO and SDO are disabled.	E hex	1	1	1	0
Reserved	3, 5, 6, 7, 9, B, D, F hex	-	-	-	-

**Table 5. DSP Calibration Coefficient Registers**

COEFFICIENT	REGISTER ADDRESS	FUNCTION	RANGE	FORMAT
Gain	1	Gain correction	-32768 to +32767	Integer
G <sub>1</sub>	2	Linear TC gain	-1.0 to +0.99997	Fraction
G <sub>2</sub>	3	Quadratic TC gain	-1.0 to +0.99997	Fraction
Of <sub>0</sub>	4	Offset correction	-1.0 to +0.99997	Fraction
Of <sub>1</sub>	5	Linear TC offset	-1.0 to +0.99997	Fraction
Of <sub>2</sub>	6	Quadratic TC offset	-1.0 to +0.99997	Fraction
D <sub>OFF</sub>	7	Output midscale pedestal	-32768 to +32767	Integer

### Writing to the DSP Registers

Command 1 hex writes calibration coefficients from the test system directly into the DSP registers. Tester commands 8 hex and C hex cause the MAX1460 to start a conversion using the calibration coefficients in the registers. This direct use of the registers speeds calibration and compensation because it does not require EEPROM write-access time. Bringing RESET low clears the DSP registers, so the test system should always write to the registers and start a conversion in a single command timing sequence.

As shown in Table 5, seven registers hold the calibration coefficients of the characteristic equation [ $D_{OUT} = \text{Gain} (1 + G_1T + G_2T^2) (\text{Signal} + Of_0 + Of_1T + Of_2T^2) + D_{OFF}$ ] implemented by the MAX1460 DSP. All of the registers are 16-bit, two's complement coding format. When a register is interpreted as an integer, the decimal range is from -32768 (8000 hex) to +32767 (7FFF

hex). Fractional coefficient values range from -1.0 (8000 hex) to +0.99997 (7FFF hex).

The register at address 0 is called the Configuration Register. It holds the coarse offset, PGA gain, Op Amp Power-Down, temperature-sensor offset, repeat mode, and reserved bits, as shown in Table 6. The functionality of the coarse offset, PGA gain, and temperature-sensor bits are described in the *Analog Front End* section.

The Op Amp Power-Down bit enables the uncommitted op amp when set. The repeat-mode bit is tested by the last instruction of the DSP microcode, and, if set, immediately initiates another conversion cycle. The Maxim reserved bits should not be altered.

# Low-Power, 16-Bit Smart ADC

**Table 6. Configuration Register Bitmap**

EEPROM ADDRESS (HEX)	BIT POSITION	DESCRIPTION

### Writing to the Internal EEPROM

The test system writes to the EEPROM with commands 4 hex (Block-Erase the entire EEPROM), 2 hex (Write "1" to a single EEPROM bit) and 0 hex (NOOP). During normal operation (when the TEST pin is low) or when the test system issues instructions A hex or E hex (Start conversion from EEPROM values), the DSP reads the Calibration Coefficients from the EEPROM.

In the normal production flow, determine the calibration coefficients using direct register access. Then load the calibration coefficients into the EEPROM with tester instruction 2 hex. Instruction 4 hex block-erases the EEPROM and is necessary only for a rework or reclaim operation. For each part, the Maxim reserved bits in the Configuration Register should be read before instruction 4 hex is issued, and restored afterwards. The MAX1460 is shipped with its internal EEPROM uninitialized, except for the reserved bits.

The internal 128-bit EEPROM is arranged as eight 16-bit words. These eight words are the configuration register and the seven calibration-coefficient values (Table 7).

The MAX1460 EEPROM is bit addressable. The final calibration coefficients must be mapped into the EEPROM locations that are to be set. There is no bit-clear instruction. Any EEPROM write operation is neces-

sarily long because the internal charge pump must create and maintain voltages above 20V long enough to cause a reliably permanent change in the memory.

Writing an EEPROM bit requires 6ms, so writing the EEPROM typically requires less than 400ms. Do not decrease the EEPROM write times.

To write an EEPROM bit, the test system must be compliant with the *Command Timing Diagram* shown in Figure 3, performing the following operations:

- 1) Issue command 0 hex, including the EEPROM address field of the bit to be written.
- 2) Issue command 2 hex, with the address field used in step 1. Continuously repeat this command 375 times (6ms).
- 3) Issue command 0 hex, including the EEPROM address field used in steps 1 and 2.

The procedure for using command 4 hex (Block-Erase the EEPROM) is similar. Record the Maxim Reserved bits in the configuration register prior to using this command, and restore them afterwards. The number of Block-Erase operations should not exceed 100.

- 1) Issue command 0 hex.
- 2) Issue command 4 hex. Continuously repeat this command 375 times (6ms).
- 3) Issue command 0 hex.

### Test System Interface: Observing the DSP Operation

Test system commands 8 hex and A hex initiate a conversion while allowing the test system to observe the operation of the DSP. To calibrate a unit, the test system must know the digitized temperature and sensor signals, stored in DSP registers 8 and 9, and the calibrated and compensated output stored in DSP register 10. The test system should also verify the EEPROM contents, registers 0–7. All these signals pass through DSP register S during the execution of the instruction ROM microcode. The SDO pin outputs the S register values, and the SDIO pin tells the tester which signal is currently on S.

There are three internal DSP registers that are directly observable on the SDIO and SDO pins:

- S: 16-bit DSP Scratch or Accumulator register, containing the result of the execution of the current microcode instruction.
- P: 8-bit DSP Program Pointer register, which holds the address of the instruction ROM microcode.
- PS: 8-bit DSP Program Store register. PS is the instruction that the DSP is currently executing. PS is the instruction ROM data at address P.

The DSP instructions relevant to the test system are listed in Table 8.

After the test system sends the Start Conversion commands 8 hex or A hex, SDIO and SDO are both enabled as MAX1460 serial outputs. The test system should disable (high impedance) its SDIO driver to avoid a bus conflict at this time so that the MAX1460 can drive the pin. After the DSP executes each one of the microcode instructions, the contents of the registers S, P, and PS are output in a serial format (Figure 4).

A new DSP instruction and a new state of the S, P, and PS registers are delivered every 16n + 9 clock cycles, where n = 0, 1, 2... after the Start Conversion command completes. The tester should latch the SDIO and SDO

# Low-Power, 16-Bit Smart ADC

**MAX1460**

Figure 4. DSP Serial Output Timing Diagram

Figure 5. MAX1460 Conversion Timing

bits on the falling edge of the XIN clock signal. When the P and PS registers in Table 8 appear on SDIO, the tester should save the corresponding SDO data.

The conversion timing of the MAX1460 is shown in Figure 5 and Table 9. In the figure, the conversion is initiated by a rising transition on the START pin. Equivalently, conversion can be initiated in TEST mode after completion of tester commands 8 hex or A hex, or reinitiated by the state of the Repeat Mode bit in the configuration register. After a conversion is initiated, the 16-bit ADC digitizes the temperature and sensor signals during  $t_{ADC}$ . Then, the DSP executes the

instruction ROM microcode during  $t_{DSP}$ . In TEST mode, and during  $t_{DSP}$ , SDIO and SDO outputs carry useful information. At 130,586 clock cycles after the Start Conversion command is received, the LSB of the S and P DSP registers is available on SDO and SDIO. The last DSP instruction is D0 hex. The tester can now start a new communication sequence by lowering the RESET pin for at least 16 clock cycles, and then resume driving SDIO. SDIO becomes high impedance when RESET is low.

EOC Pulse Width	t <sub>EOC</sub>	8	8	XIN clk cycles
Conversion Time	t <sub>CONV</sub>	133,805	133,949	XIN clk cycles

## Applications Information

### Calibration and Compensation Procedure

Perform fine calibration by characterizing the sensor/MAX1460 pair using the test system and then finding the calibration coefficients Gain, G<sub>1</sub>, G<sub>2</sub>, Of<sub>0</sub>, Of<sub>1</sub>, and Of<sub>2</sub> using the equations below. This simple fine-calibration procedure requires three temperatures, denoted A, B, and C, and two sensor excitations, named S and L for small and large. Thus, there are six data points (AS, AL, BS, BL, CS, and CL); six unknown calibration coefficients; and six versions of the characteristic equation, in the form:

Equation (1)

$$D_L - D_{OFF} = \text{Gain} \left( 1 + G_1 T_C + G_2 T_C^2 \right) \left( \text{Signal}_{CL} + Of_0 + Of_1 T_C + Of_2 T_C^2 \right)$$

where D<sub>L</sub>, D<sub>S</sub>, and D<sub>OFF</sub> are determined by the end product specification. D<sub>L</sub> is the desired MAX1460 output corresponding to the L sensor excitation; D<sub>S</sub> is the desired MAX1460 output corresponding to the S sensor excitation; D<sub>OFF</sub> is the desired midscale output; Signal<sub>CL</sub> is the digitized sensor reading at temperature C with the L sensor excitation applied; and T<sub>C</sub> is the digitized temperature reading at temperature C.

Unstable digitized temperature readings indicate that thermal equilibrium has not been achieved, necessitating increased soak times or a better thermal control. Averaging many readings from the MAX1460 will help filter out AC variations in the sensor excitation and oven temperature.

Begin calibration by soaking the sensor and the MAX1460 pair at the first temperature, A, and apply the L excitation to the sensor. Start a conversion and record the digitized temperature T<sub>A</sub> and the digitized signal Signal<sub>AL</sub>. Apply the S sensor excitation, and record the digitized signal Signal<sub>AS</sub>. Repeat this procedure for temperatures B and C, recording T<sub>B</sub>, Signal<sub>BL</sub>, Signal<sub>BS</sub>, T<sub>C</sub>, Signal<sub>CL</sub>, and Signal<sub>CS</sub>.

The AL and AS versions of equation 1 may be ratioed to obtain:

Equation (2a)

$$\frac{\text{Signal}_{AL} - x \cdot \text{Signal}_{AS}}{1 - x} + Of_0 + Of_1 T_A + Of_2 T_A^2 = 0$$

Similarly,

Equation (2b)

$$\frac{\text{Signal}_{BL} - x \cdot \text{Signal}_{BS}}{1 - x} + Of_0 + Of_1 T_B + Of_2 T_B^2 = 0$$

Equation (2c)

$$\frac{\text{Signal}_{CL} - x \cdot \text{Signal}_{CS}}{1 - x} + Of_0 + Of_1 T_C + Of_2 T_C^2 = 0$$

where

Equation (3)

$$x = \frac{D_L - D_{OFF}}{D_S - D_{OFF}}$$

Equations 2a, 2b, and 2c form a system of three linear equations, with three unknowns, Of<sub>0</sub>, Of<sub>1</sub>, and Of<sub>2</sub>. Solve for Of<sub>0</sub>, Of<sub>1</sub>, and Of<sub>2</sub>.

The small sensor excitation versions of Equation 1 can be ratioed to obtain:

Equation (4a)

$$(Y_{CS} - Y_{AS}) + G_1 (T_A Y_{CS} - T_C Y_{AS}) + G_2 (T_A^2 Y_{CS} - T_C^2 Y_{AS}) = 0$$

Equation (4b)

$$(Y_{CS} - Y_{BS}) + G_1 (T_B Y_{CS} - T_C Y_{BS}) + G_2 (T_B^2 Y_{CS} - T_C^2 Y_{BS}) = 0$$

# Low-Power, 16-Bit Smart ADC

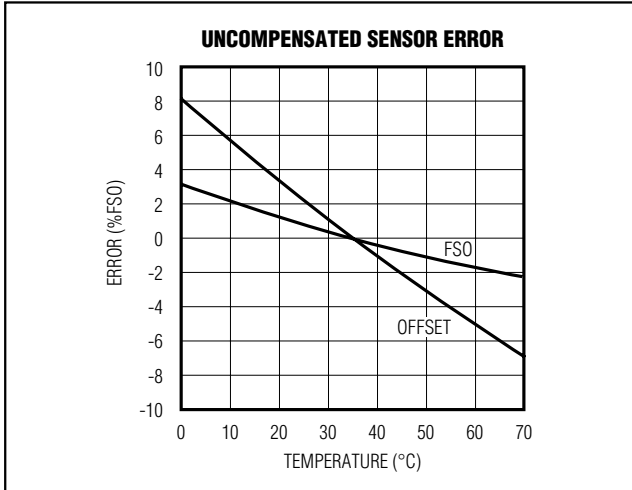

Figure 6. Sensor Characteristics Before Compensation

Figure 8. Filtering the Output DAC

Figure 7. Compensated Sensor/MAX1460 Pair

where:

Equation (5a)

$$Y_{AS} = \frac{D_S - D_{OFF}}{\text{Signal}_{AS} + Of_0 + Of_1 T_A + Of_2 T_A^2}$$

Equation (5b)

$$Y_{BS} = \frac{D_S - D_{OFF}}{\text{Signal}_{BS} + Of_0 + Of_1 T_B + Of_2 T_B^2}$$

Equation (5c)

$$Y_{CS} = \frac{D_S - D_{OFF}}{\text{Signal}_{CS} + Of_0 + Of_1 T_C + Of_2 T_C^2}$$

Equations 4a and 4b form a system of two linear equations and two unknowns,  $G_1$  and  $G_2$ . Solve for  $G_1$  and  $G_2$ . Equation 1 can now be readily solved for the last unknown, Gain.

Arithmetic manipulation can magnify measurement errors and noise. Quantization of the calibration coefficients is another reason to consider adjusting the Gain and  $D_{OFF}$  coefficients. To do this, load the MAX1460 registers with the calculated coefficients Gain,  $G_1$ ,  $G_2$ ,  $Of_0$ ,  $Of_1$ ,  $Of_2$ , and  $D_{OFF}$ . Assuming the oven is still at temperature C and the S sensor excitation is still applied, measure the output  $D_{CS}$ . Change to the L sensor excitation, and measure  $D_{CL}$ . Compute the new Gain coefficient using equation 6. Remeasure  $D_{CL}$ , and compute the new  $D_{OFF}$  coefficient, given by equation 7.

Equation (6)

$$\text{GAIN}_{\text{new}} = \text{Gain} \frac{D_L - D_S}{D_{CL} - D_{CS}}$$

Equation (7)

$$D_{OFF_{\text{new}}} = D_{OFF} + D_L - D_{CL}$$

The final calibration coefficients may now be written into the MAX1460 EEPROM. The unit is now ready for final test.

## Low-Power, 16-Bit Smart ADC

This algorithm minimizes the error directly at the six test conditions, AS, AL, BS, BL, CS, and CL. Space the temperatures A, B, and C widely to minimize the signal-to-noise ratio of the measurement. If there is a large error remaining in the finished product, move the calibration temperatures closer to the peak error temperatures. Similarly, full-scale sensor excitation may not be the best calibration condition if the sensor has non-linearities. Move S and L away from full scale.

Figure 6 shows the characteristics of an individual Lucas-NovaSensor model NPH8-100-EH, 0 to 15psig, silicon pressure sensor. Figure 7 shows the result of the compensated sensor/MAX1460 pair.

### Using the Compensated Sensor/MAX1460 Pair

After calibration and removal from the test system, the MAX1460 and the sensor form a mated pair. The START pin can be connected to  $V_{DD}$  or left unconnected if the sensor does not require a significant warm-up time. Now operation is simple: just apply power and latch the parallel output D when EOC falls. Temperature is digitized during the first half of  $t_{ADC}$ , so the MAX1460 provides a minimum sensor warm-up time of 35ms. Using a 2MHz resonator, the conversion time  $t_{CONV}$  is nominally 67ms. If the Repeat Mode bit is set, conversions repeat at a rate of 15Hz.

If the sensor requires more than 35ms of warm-up time, the START pin may be used to initiate conversion (Figure 5). If the Repeat Mode bit is set, START should remain high. If the Repeat Mode bit is reset, START may be used to externally control the conversion rate of the MAX1460. After the 12-bit parallel output D is latched, end the conversion by taking START low for at least one clock cycle.

The output DAC converts the parallel digital output into a serial bitstream on OUT. A simple external lowpass filter, using the MAX1460 op amp, converts the OUT bitstream into a ratiometric analog voltage (Figure 8). The filter shown is an inverting configuration, but the Gain and D<sub>OFF</sub> coefficients of the characteristic equation can be adjusted to obtain either polarity. If the op amp is not used, it can be powered down using the Op Amp Power-Down bit in the configuration register.

The MAX1460 requires a minimum of external components:

- One power-supply bypass capacitor (C1) from  $V_{DD}$  to  $V_{SS}$ .
- One 2MHz ceramic resonator (X1).
- Two 10k $\Omega$  resistors for the AGND pin.
- If an analog output is desired, two 500k $\Omega$  resistors and a 1 $\mu$ F capacitor are needed for filtering.

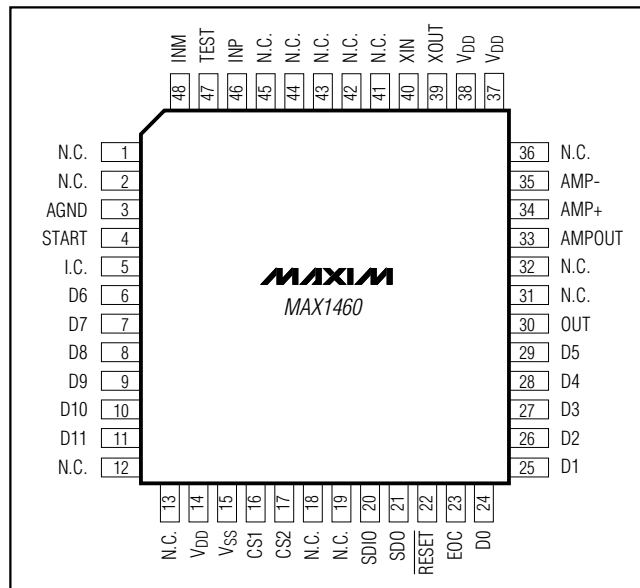

### MAX1460 Evaluation/Development Kit

The MAX1460 evaluation kit (EV kit) speeds the development of MAX1460-based transducer prototypes and test systems. First-time users of the MAX1460 are strongly encouraged to use this kit, which includes:

- 1) Evaluation board, with a MAX1460 sample and a silicon pressure sensor, ready for customer evaluation.
- 2) Interface board that must be connected to a PC parallel port.
- 3) MAX1460 communication/compensation software (Windows compatible), which enables programming of the MAX1460 one module at a time.
- 4) Detailed Design/Applications manual, developed for sensor-test engineers.

The evaluation kit order number is MAX1460EVKIT.
